Chapter 14: Transactions

SET OF OPERATIONS: E.G. MONEY TRANSFER FROM ONE BANK ACCOUNT TO ANOTHER

SINGLE OPERATION FROM A LOGICAL POINT OF VIEW — EXECUTED AS IF IT WAS A SINGLE ATOMIC OPERATION [ALL OR NOTHING]

BY MEANS OF TRANSACTIONS, A DBMS CAN GUARANTEE SOME DESIRED PROPERTIES REGARDED TO FAILURE HANDLING AND CONCURRENT EXECUTION

Outline

- Transaction Concept
- Transaction State
- Concurrent Executions
- Serializability
- Recoverability
- Implementation of Isolation
- Transaction Definition in SQL
- Testing for Serializability.

Transaction Concept

- A **transaction** is a *unit* of program execution that accesses and possibly updates various data items.
- E.g., transaction to transfer $50 from account A to account B:
  1. **read**(*A*)
  2. *A* := *A* – 50
  3. **write**(*A*)
  4. **read**(*B*)
  5. *B* := *B* + 50
  6. **write**(*B*)

THE READ AND WRITE OPERATIONS, AS WE SHALL SEE, ARE THE MOST IMPORTANT UNDER OUR POINT OF VIEW AS THEY ARE THE ONES INTERACTING WITH THE DATABASE CONTENT

- Two main issues to deal with:
  - Failures of various kinds, such as hardware failures and system crashes
  - Concurrent execution of multiple transactions

Required Properties of a Transaction

- Consider a transaction to transfer $50 from account A to account B:
  1. **read**(*A*)
  2. *A* := *A* – 50
  3. **write**(*A*)
  4. **read**(*B*)
  5. *B* := *B* + 50
  6. **write**(*B*)

THERE ARE SOME PROPERTIES THAT MUST BE GUARANTEED DURING TRANSACTION EXECUTION, TO PREVENT UNWANTED BEHAVIOURS FROM HAPPENING IN THE EVENT OF FAILURE OR CONCURRENT ACCESS

- **Atomicity requirement** (EITHER ALL OR NOTHING)
  - If the transaction fails after step 3 and before step 6, money will be "lost" leading to an inconsistent database state
    - Failure could be due to software or hardware
  - The system should ensure that updates of a partially executed transaction are not reflected in the database
- **Durability requirement** — once the user has been notified that the transaction has completed (i.e., the transfer of the $50 has taken place), the updates to the database by the transaction must persist even if there are software or hardware failures.

Required Properties of a Transaction (Cont.)

A TRANSACTION BEGINS FROM A CONSISTENT DB AND LEAVES IT IN A CONSISTENT STATE AFTER ITS EXECUTION –

- **Consistency requirement** in above example:
  - The sum of A and B is unchanged by the execution of the transaction
- In general, consistency requirements include
  - Explicitly specified integrity constraints such as primary keys and foreign keys
  - Implicit integrity constraints
    - e.g., sum of balances of all accounts, minus sum of loan amounts must equal value of cash-in-hand
- A transaction, when starting to execute, must see a consistent database.
- During transaction execution the database may be temporarily inconsistent.
- When the transaction completes successfully the database must be consistent
  - Erroneous transaction logic can lead to inconsistency

THUS, DURING TRANSACTION EXECUTION YOU MAY VIOLATE CONSTRAINTS - THEY HAVE NEVERTHELESS TO BE SATISFIED BY THE END OF THE TRANSACTION

Required Properties of a Transaction (Cont.)

- **Isolation requirement** — if between steps 3 and 6 (of the fund transfer transaction) , another transaction **T2** is allowed to access the partially updated database, it will see an inconsistent database (the sum $A + B$ will be less than it should be).

CONCURRENT TRANSACTIONS SHOULD NOT INTERFERE WITH EACH OTHER

T1	T2
1. **read**(A)	
2. $A := A - 50$	
3. **write**(A)	
	read(A), read(B), print(A+B)
4. **read**(B)	
5. $B := B + 50$	
6. **write**(B)	

WE WANT TO ALLOW THE EXECUTION OF A CONCURRENT SET OF TRANSACTIONS IN SUCH A WAY THAT THE RESULT OF SUCH CONCURRENT EXECUTION IS THE SAME AS THAT OF A SERIAL EXECUTION OF THE TRANSACTIONS.

THERE CAN BE MANY DIFFERENT SERIAL ORDERINGS, ANY OF THEM IS OK FOR US

SO, WE ARE NOT INTERESTED IN THE OUTCOME PER SE. IT JUST NEEDS TO BE ONE OF THE POSSIBLE ONES.

BUT WE CANNOT SIMPLY COMPARE OUR RESULTS WITH THOSE OF ANY POSSIBLE SERIAL EXECUTION OF THE SET OF TRANSACTIONS, TO SEE IF THERE IS ONE THAT MATCHES IT... THEY ARE TOO MANY! (FACTORIAL)

NEED OF SOME HEURISTICS TO DO THAT

- Isolation can be ensured trivially by running transactions **serially**
  - That is, one after the other.
- However, executing multiple transactions concurrently has significant benefits, as we will see later.

- INEFFICIENT ⇝ THINK ABOUT AN AIRLINE COMPANY
- UNNECESSARY ⇝ CONSTRAIN THE INTERACTION ONLY BETWEEN CRITICAL TRANSACTIONS

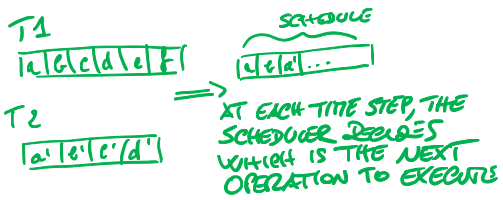
ACID Properties

A **transaction** is a unit of program execution that accesses and possibly updates various data items. To preserve the integrity of data the database system must ensure:

- **Atomicity.** Either all operations of the transaction are properly reflected in the database or none are.
- **Consistency.** Execution of a transaction in isolation preserves the consistency of the database.
- **Isolation.** Although multiple transactions may execute concurrently, each transaction must be unaware of other concurrently executing transactions. Intermediate transaction results must be hidden from other concurrently executed transactions.
  - That is, for every pair of transactions T_i and T_j, it appears to T_i that either T_j, finished execution before T_i started, or T_j started execution after T_i finished.
- **Durability.** After a transaction completes successfully, the changes it has made to the database persist, even if there are system failures.

Transaction State

- **Active** – the initial state; the transaction stays in this state while it is executing
- **Partially committed** – after the final statement has been executed.
- **Failed** -- after the discovery that normal execution can no longer proceed.
- **Aborted** – after the transaction has been rolled back and the database restored to its state prior to the start of the transaction. Two options after it has been aborted:
  - Restart the transaction
    - can be done only if no internal logical error
  - Kill the transaction
- **Committed** – after successful completion.



Schedules

- **Schedule** – a sequences of instructions that specify the chronological order in which instructions of concurrent transactions are executed
  - A schedule for a set of transactions must consist of all instructions of those transactions
  - Must preserve the order in which the instructions appear in each individual transaction.

IN THE EXAMPLE ABOVE, I CANNOT HAVE "c" COMING BEFORE "a"

- A transaction that successfully completes its execution will have a **commit** instructions as the last statement
  - By default transaction assumed to execute commit instruction as its last step
- A transaction that fails to successfully complete its execution will have an **abort** instruction as the last statement

AT COMMIT INSTANT, ALL OPERATIONS TAKE BY THE TRANSACTION ON THE DATABASE BECOME PERMANENT

Schedule 1

- Let T_1 transfer \$50 from *A* to *B*, and T_2 transfer 10% of the balance from *A* to *B*.
- An example of a **serial** schedule in which T_1 is followed by T_2 :

T_1	T_2
read (A)	
$A := A - 50$	
write (A)	
read (B)	
$B := B + 50$	
write (B)	
commit	
	read (A)
	$temp := A * 0.1$
	$A := A - temp$
	write (A)
	read (B)
	$B := B + temp$
	write (B)
	commit

Schedule 2

- A **serial** schedule in which T_2 is followed by T_1 :

T_1	T_2
	read (A) $temp := A * 0.1$ $A := A - temp$ write (A) read (B) $B := B + temp$ write (B) commit
read (A) $A := A - 50$ write (A) read (B) $B := B + 50$ write (B) commit	

OF COURSE, THEY GIVE RISE TO TWO DIFFERENT RESULTS –

Schedule 3

- Let T_1 and T_2 be the transactions defined previously. The following schedule is not a serial schedule, but it is **equivalent** to Schedule 1.

T_1	T_2
read (A)	
$A := A - 50$	
write (A)	
	read (A)
	$temp := A * 0.1$
	$A := A - temp$
	write (A)
read (B)	
$B := B + 50$	
write (B)	
commit	
	read (B)
	$B := B + temp$
	write (B)
	commit

Note -- In schedules 1, 2 and 3, the sum “A + B” is preserved.

Schedule 4

- The following concurrent schedule does not preserve the sum of "$A + B$"

T_1	T_2
read (A)	
$A := A - 50$	
	read (A)
	$temp := A * 0.1$
	$A := A - temp$
	write (A)
	read (B)
write (A)	
read (B)	
$B := B + 50$	
write (B)	
commit	
	$B := B + temp$
	write (B)
	commit

WHICH IS STILL THE ORIGINAL VALUE, WITHOUT THE SUBTRACTION

THE RESULT CANNOT BE OBTAINED WITH ANY SERIAL EXECUTION OF T_1 AND T_2 –

YOU ARE LOSING AN UPDATE OF "A" HERE–

WE WANT A WAY TO ACCEPT SCHEDULE 3 AND REJECT SCHEDULE 4 ... A FAIRLY EASY WAY, COMPUTATIONALLY SPEAKING –

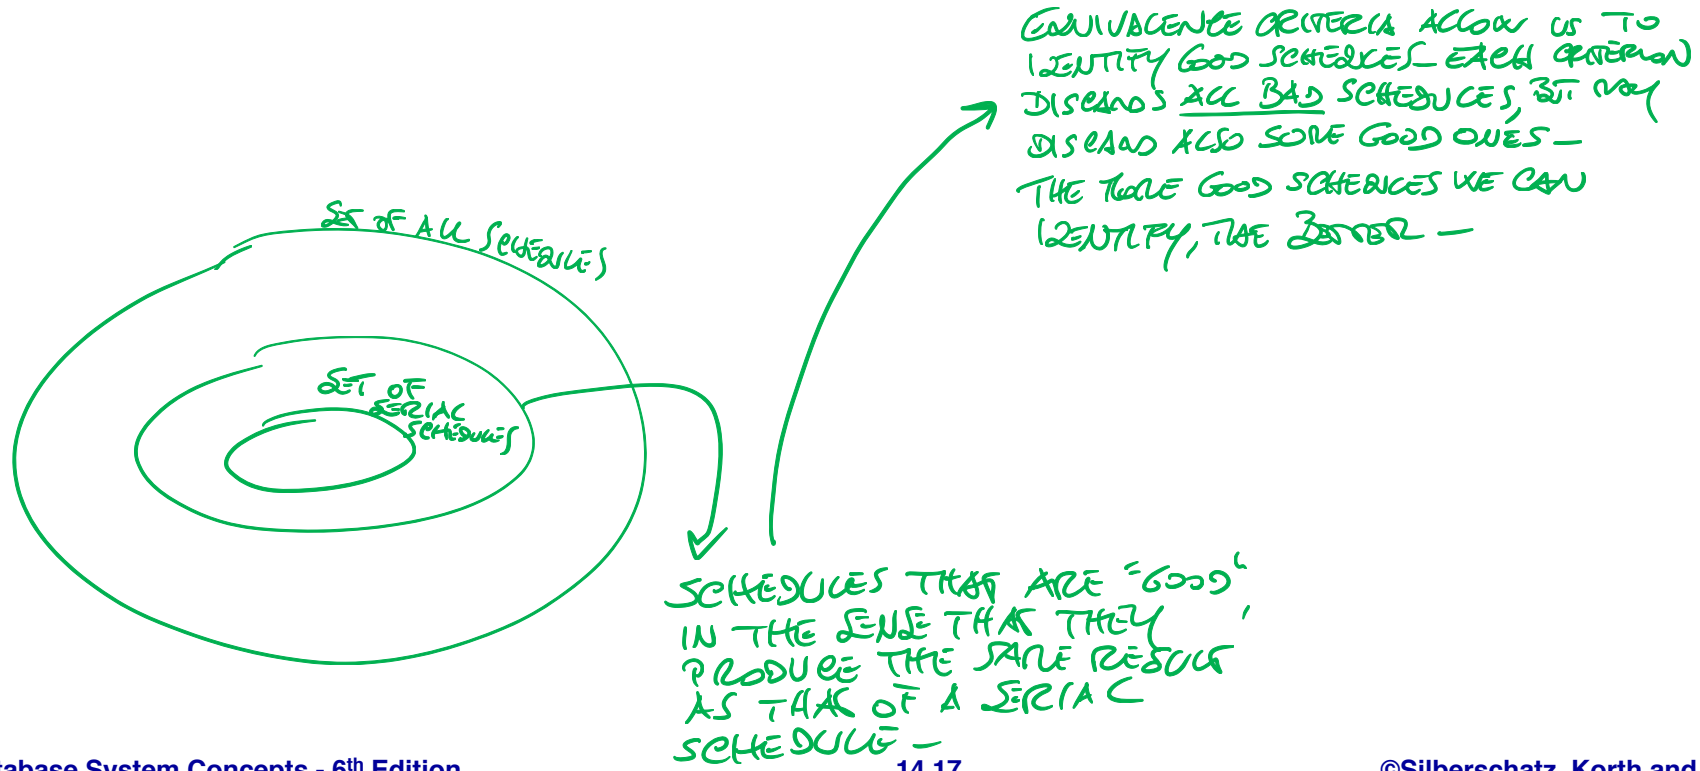
Serializability

- **Basic Assumption** – Each transaction preserves database consistency.
- Thus, serial execution of a set of transactions preserves database consistency.
- A (possibly concurrent) schedule is serializable if it is equivalent to a serial schedule. Different forms of schedule equivalence give rise to the notions of:
  1. **conflict serializability** → THIS WILL BE OUR HEURISTIC

INSTEAD OF HAVING TO COMPARE OUR RESULT WITH THAT OF ANY POSSIBLE SERIAL SCHEDULE OF THE TRANSACTIONS

Simplified view of transactions

- We ignore operations other than **read** and **write** instructions
- We assume that transactions may perform arbitrary computations on data in local buffers in between reads and writes.
- Our simplified schedules consist of only **read** and **write** instructions.



Conflicting Instructions

- Let I_i and I_j be two instructions of transactions T_i and T_j respectively. Instructions I_i and I_j **conflict** if and only if there exists some item Q accessed by both I_i and I_j, and at least one of these instructions wrote Q.
  1. I_i = **read**(Q), I_j = **read**(Q). I_i and I_j don't conflict.
  2. I_i = **read**(Q), I_j = **write**(Q). They conflict.
  3. I_i = **write**(Q), I_j = **read**(Q). They conflict
  4. I_i = **write**(Q), I_j = **write**(Q). They conflict
- Intuitively, a conflict between I_i and I_j forces a (logical) temporal order between them.
  - If I_i and I_j are consecutive in a schedule and they do not conflict, their results would remain the same even if they had been interchanged in the schedule.

"Q" STANDS FOR AN ITEM, WHICH IS A GENERAL CONCEPT ⟹ CAN BE COLUMN, A ROW, A TABLE, ...

Conflict Serializability

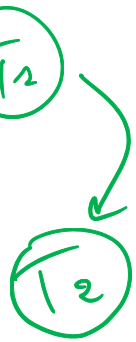
- If a schedule *S* can be transformed into a schedule *S'* by a series of swaps of non-conflicting instructions, we say that *S* and *S'* are **conflict equivalent**.
- We say that a schedule *S* is **conflict serializable** if it is conflict equivalent to a serial schedule

Conflict Serializability (Cont.)

PAIRS IN CONFLICT = $\{(T_1(A), W_2(A)), (W_1(A), R_2(A)), (W_1(A), W_2(A)), (R_1(B), W_2(B)), (W_1(B), R_2(B)), (W_1(B), W_2(B))\}$

- Schedule 3 can be transformed into Schedule 6 -- a serial schedule where T_2 follows T_1, by a series of swaps of non-conflicting instructions. Therefore, Schedule 3 is conflict serializable.

CONFLICT GRAPH:



T_1	T_2
read (A)	
write (A)	
	read (A)
	write (A)
read (B)	
write (B)	
	read (B)
	write (B)

Schedule 3

T_1	T_2
read (A)	
write (A)	
read (B)	
write (B)	
	read (A)
	write (A)
	read (B)
	write (B)

Schedule 6

THUS, SCHEDULE 3 IS A "GOOD" ONE, SINCE IT CAN BE TRANSFORMED INTO SCHEDULE 6, WHICH IS SERIAL, AND THE FINAL RESULT OF THE TWO SCHEDULES IS THE SAME.

Conflict Serializability (Cont.)

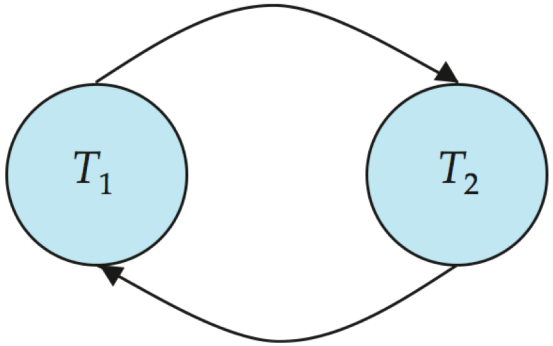
- Example of a schedule that is not conflict serializable:

T_3	T_4
read (Q)	
	write (Q)
write (Q)	

- We are unable to swap instructions in the above schedule to obtain either the serial schedule < T_3, T_4 >, or the serial schedule < T_4, T_3 >.

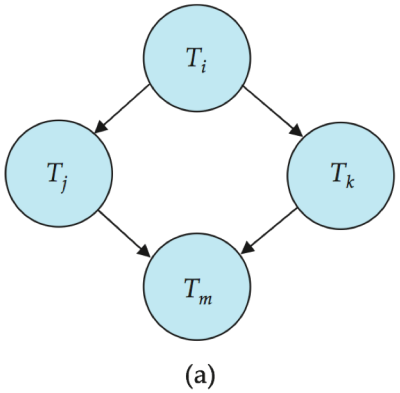
Precedence Graph

- Consider some schedule of a set of transactions T_1, T_2, ..., T_n
- **Precedence graph** — a direct graph where the vertices are the transactions (names).
- We draw an arc from T_i to T_j if the two transaction conflict, and T_i accessed the data item on which the conflict arose earlier.
- We may label the arc by the item that was accessed.
- **Example**

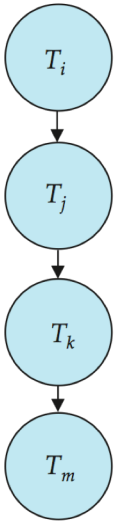


Testing for Conflict Serializability

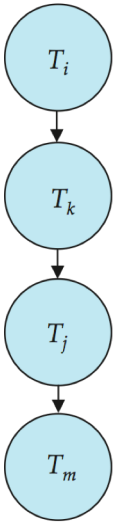
- A schedule is conflict serializable if and only if its precedence graph is acyclic.
- Cycle-detection algorithms exist which take order n^2 time, where n is the number of vertices in the graph.
  - (Better algorithms take order $n + e$ where e is the number of edges.)
- If precedence graph is acyclic, the serializability order can be obtained by a *topological sorting* of the graph.
  - That is, a linear order consistent with the partial order of the graph.
  - For example, a serializability order for the schedule (a) would be one of either (b) or (c)



(a)



(b)



(c)
